

场效应管

MOSFET

1. V_{GS} 对半导体表面空间电荷区状态的影响

当 V_{GS} 逐渐增大时，栅氧化层下方的半导体表面会发生什么变化？

(1) $V_{GS} = 0$

漏源之间相当于两个背靠背的 PN 结，无论漏源之间加何种极性电压，总是不导电

(2) $V_{GS} > 0$ 逐渐增大

栅氧化层中的场强越来越大，它们排斥P型衬底靠近 SiO_2 一侧的空穴，形成由负离子组成的耗尽层，增大 V_{GS} 耗尽层变宽

(3) V_{GS} 继续增大

由于吸引了足够多P型衬底的电子，会在耗尽层和 SiO_2 之间形成可移动的N型薄层，称为反型层，这个反型层就构成了漏源之间的导电沟道。这时，在 V_{DS} 的作用下就会形成 I_D 。

当 V_{GS} 继续升高时，沟道加厚，沟道电阻减少，在相同 V_{DS} 的作用下， I_D 将进一步增加。

MOSFET能够工作的关键是半导体 表面必须有导电沟道。

使沟道刚刚形成所需加的栅源电压称为开启电压，用 V_T 表示。

2. V_{DS} 对导电沟道的影响

($V_{GS} > V_T$)

(1) $V_{DS} > 0$, 但值很小时

V_{DS} 对沟道影响可忽略, 沟道厚度均匀

(2) $0 < V_{DS} < V_{GS} - V_T$,

即 $V_{GD} = V_{GS} - V_{DS} > V_T$

导电沟道呈现一个楔形, 靠近漏端的导电沟道减薄

(3) $V_{DS} = V_{GS} - V_T$, 即 $V_{GD} = V_T$

靠近漏极沟道出现夹断点, 称为预夹断

(4) $V_{DS} > V_{GS} - V_T$, 即 $V_{GD} < V_T$

夹断区发生扩展, V_{DS} 的增大几乎全部用来克服夹断区的电阻, I_D 几乎仅决定于 V_{GS}

(1) V_{DS} 很小

(2) $V_{DS} \uparrow$: $V_{GD} > V_T$

(3) $V_{DS} \uparrow \uparrow$: $V_{GD} = V_T$

(4) $V_{DS} \uparrow \uparrow \uparrow$: $V_{GD} < V_T$

Linear operating region (ohmic mode)

Saturation mode at point of pinch-off

Saturation mode

3. MOSFET的特性曲线

(1) 漏极输出特性曲线

不同 V_{GS} 下，漏极电流 I_D 与漏源电压 V_{DS} 之间的关系曲线族

- (a) 截止区: $V_{GS} < V_T$
- (b) 可变电阻区: $V_{DS} \leq (V_{GS} - V_T)$
- (c) 恒流区(饱和区): $V_{GS} > V_T$, 且 $V_{DS} \geq (V_{GS} - V_T)$
- (d) 击穿区: V_{DS} 继续增大到漏结发生雪崩击穿, I_D 急剧增大

(2) 转移特性曲线

漏源电压 V_{DS} 一定的条件下，栅源电压 V_{GS} 对漏极电流 I_D 的控制特性

n-channel device

p-channel device

Enhancement
NFET

No gate-source voltage,
poorly conducting
channel

(a)

Positive gate-source
voltage applied,
channel enhanced

n-channel MOSFET, or NMOSFET or NFET

- Source-drain current carried by electrons in the channel
- Substrate is p-type semiconductor (because carriers in channels are from inversion)

Enhancement
PFET

No gate-source voltage,
poorly conducting
channel

(b)

Negative gate
voltage applied,
channel enhanced

p-channel MOSFET, or PMOSFET, or PFET

- Source-drain current carried by holes in the channel
- Substrate is n-type semiconductor

Depletion
NFET

No gate-source voltage,
channel exists

(c)

Negative gate-source
voltage applied,
channel depleted

Enhancement mode MOSFET

- No conduction channel exists between source and drain when gate bias is zero
- Need an applied gate bias to “enhance” the conduction channel (turn on the device)

Depletion mode MOSFET

- A conduction channel exists when gate bias is zero
- Need an applied gate bias to “deplete” carriers in channel (turn off the device)

Depletion
PFET

No gate-source voltage,
channel exists

(d)

Positive gate-source
voltage applied,
channel depleted
